

Module 2 Recorded Discussion and Journal

1. Can we really compare how the human brain works with the computer, and how do we compare them in relation to acquiring information, how information is being processed?

We can compare the human brain to the computer because of its similar functions. Humans created computers to work tirelessly, and since Humans created computers, we can say that it functions the same as a human brain because the computer was designed to work like a human brain. It acquires information, processes information, and stores information like a human brain.

2. How does problem solving vary from reasoning? Cite an example or give a scenario and then differentiate problem solving and reasoning.

Solving problems and reasoning can be defined as cognitive actions that are often combined here and there but are different in their functions. In problem-solving there are issues to be solved to arrive at a specific outcome and solve day to day problems. Reasoning refers to the process of making conclusions from the information gathered. Their goals are correlated but their use and approach are different. A good example scenario is when you are preparing for an exam, you are studying for an exam and you do not fully understand the topic. Problem solving would be you will read text books, watch study videos, and ask a classmate for help. Where reasoning assists in self testing to determine whether you have grasped the concept or by comparing your solutions against model solutions. If, for example, you repeatedly answer questions incorrectly, then your reasoning faculty may make you believe that you require more practice or that you did not understand.

3. Provide sample that applies the gestalt theory

1. Continuity

A curved road on a map is a continuous path instead of a series of disconnected lines.

2. Symmetry

A butterfly illustration is balanced, its left and right sides are symmetrical.

3. Similarity

The Similarity of shape in traffic lights are the circles, it allows us to group them as a signal system.

4. Proximity

A Dining setup is a good example of proximity, since chairs and tables are seen together most of the time which puts them in a same category

5. Closure

The WWF panda logo is formed with incomplete lines, but it is still recognized as a panda.

6. Figure and Ground

The Figure and Ground principle is focused on how the mind appears to process information or figures in relation to a background; in fact, this is the process that allows us to understand a complex image or a background.
